Turk salty fiber concrete is designed to isolate retaining walls against saline materials. In 2018, TSFC mixture design was applied to the salt domes in the GOTVAND reservoir dam, SE of Iran in order to isolate them enormous salt ridges were discovered inside the dam reservoir before construction operations began in 2005 which are also identifiable through the use of geotechnical maps. The designed mixture of TSFC contains salt stone (S), water (W), cement type II (CII), bentonite (B), clay (C) and cotton or synthetic fibers (F). In the laboratory, TSFC is produced taking into account the variable of saline water. The figure $\zeta$ is defined by the proportion of the weight of the salt and water over the weight of the combined mixture of cement, bentonite, clay and fibers. The maximum value $\zeta$ has been obtained as being a bit over 6.5 for laboratory samples. It means that more than 87% of the sample weight is related to saline water and 13% is related to other materials (CII, B, C and F). The axial load test is the main index to compare resistance with friction of salt formations. The results obtained show the axial resistance of broken TSFC samples to be more 12,000 KPA. SEM images were taken to study TSFC adhesiveness between the salt and fibers. The SEM showed cubic crystallization which in itself supports the hypothesis of salty mummification due to the integrating of the salt concrete and fibers.

Keywords: Axial load, Mixture, Injection, Salty concrete, Mummy, Crystallization.

1 INTRODUCTION

Concrete structures are damaged by the salt water effects along coastlines. Chloride ions penetrate into concrete surface and bring about steel rebar corrosion. In order to protect the dry-wet zone against the incurring of extra costs and time, necessary preparation is required (Figure 2). The production of adhesive TSFC in recent years has led to a decline in sea water issues impact, in as such that it has been applied to stabilize salt domes, sinkholes, land slide stabilization, coastline protection and intrusion of deserts as a result of manmade droughts in Figure 1 (Gutiérrez and Lizaga 2016, Turk 2017, Turk 2018). Although TSFC was initially believed that cement and salt do not have a strong adhesiveness, the primary design mixture which was composed of salt, cement, green bentonite and clay in 2016 showed that after saturation the concrete hardened perfectly and had no sedimentations. Mixture design samples were broken up to study the behavior of the modulus of elasticity under a compressive jack. The modulus of elasticity and axial stress fluctuated due to the sensitivity of clay and bentonite. Moreover, by adding fiber, a variation in the hardening behavior of the concrete was observed. Mechanical characteristics such as axial stiffness, integration resistance in saturation mode and mummifying also improved (Waltari 1945).
TSFC continuity cohesion was demonstrated by interpreting the results obtained through SEM (scanning electron microscope) images (CENLAB 2019). Images portrayed the uniformity, mummifying, and fibers continuity.

2 MATERIALS OF TSFC

TSFC improves and increases the modulus of elasticity and cohesion resistance during the saturation phase. Samples in Figure 5, have been immersed into water since 2016 (KTNSE 2016, KTNSE 2017, KTNSE 2018, KTNSE 2019, Turk 2017, Turk 2018). Although, the samples are broken, all of them have stable shapes in the water. It has been proposed to use cotton or plastic fibers as additional material TSFC materials contain the salt stone (S), water (W), cement type II or V (Cii, Cv), Shushtar ceramic clay (C), bentonite (B) and fibers (F). Eq. (1) defines the main TSFC figure $\zeta_{Turk}$ which represents the amount of saline water in the sample. The values of $\zeta_{Turk}$ varies from 0.56 to 3.70 for fibers. Eq. (2) defines the TSFC resistance index which is represented by $\mu_{Turk}$. Figure $\mu_{Turk}$ is the combination of the axial resistance of sample S950713 after 10 days of aging and $\zeta_{Turk1}$ shows the amount of saline water after 10 days of aging Table 1 presents the TSFC
materials with the values of $\zeta_{Turk}$ and $\mu_{Turk}$ in the mixture design and the modulus of elasticity. Table 1 represents the behavior of materials vs. the $\mu_{Turk}$ of samples after 10 days of aging.

3 TSFC ELASTICITY MODULUS

Samples were broken vertically so that the modulus of elasticity could be obtained directly from the linear part in Figure 4, and Eq. (3). Axial stiffness $K$ could be increased by index of $\mu_{Turk}$ up to a period of 120 days of aging. $K$ is denoted by Eq. (4) and is capable of being interpreted using the Step Stiffness Method (SSM) (Turk and Zaemeri 2004). $F_Z$ in Eq. (4) represents the exerted vertical load in the z-z direction or as an injected wall in salt dome (Figure 2 and Figure 3).

$$E_Z = \frac{\delta}{\Delta \sigma} f(\sigma) = f'_{\sigma} = \Delta \sigma/\Delta \varepsilon = (\sigma_Y - \sigma_0)Z/(\varepsilon_Y - \varepsilon_0)Z$$  \hspace{1cm} (3)

$$K = \frac{\delta}{\Delta \varepsilon} f(F_Z) = \Delta F_{Z}/\Delta \varepsilon = \frac{\sigma A}{\varepsilon L} = E \frac{A}{L}$$  \hspace{1cm} (4)

4 SEM IMAGES

Figure 6 and Figure 7 are presented by SEM of 24-S980701C20 after 20 days of aging. Pictures were taken to study the micro behaviors of TSFC adhesiveness. It was observed that the nature of the cotton fibers had changed and had merged with the TSFC salt crystallizations. In other words, cotton fibers in the chemical composition of salt take on the characteristics of a salt mummy. It may be argued that the method of making TSFC is actually based on ancient mummification techniques (Waltari 1945). Figure 6 is an enlarged view showing the salt and fiber adhesion status (salt crystallizations). The fibers are interestingly combined with TSFC so that the fiber and the concrete are not distinguishable. Figure 5 shows a 20 $\mu$m scale cotton fiber with salt crystals impregnated within it and completely transformed into salt concrete. Figure 7 also shows the cotton fibers from another angle. 24S980701C20 shows that the salt is wrapped around the cotton fiber and integrated with it. Salt penetrates the fibers to form a uniform mixture which is parallel to the method of mummification practiced in the ancient past.

5 CONCLUSION

Table 1 is described \(\mu_{\text{Turk}}\) and \(\zeta_{\text{Turk}}\) that both are interpreted the TSFC behaviors. The salt ratio to other materials such as cement, bentonite and clay is increasing. Modulus of elasticity with salt ratio has been rising. Tri-axial tests result show that the lateral pressures greatly improve the elasticity and other properties of the TSFC more than 200%. It is therefore recommended that high-pressure injection be performed at several stages to remove excess TSFC water contain. This method can increase the injection efficiency in aquifers near the shorelines. Sea water makes a great disaster with intrusion into the underground fresh water. Based on the laboratory outcomes, TSFC has the ability to retrieve itself cracks after the initial breaking, and the TSFC regains its initial strength after a few hours. This fact is illustrated by Figure 4 (sample 37RT-TA1-7-32 curve). This property can be very useful in salty desert stabilization and coastlines layers that are restored after TSFC cracking. Scanning electron microscope (SEM) images can be used to show better adhesion of TSFC materials. The samples are remarkably mixed and difficult to separate. The salt penetrates into the cotton (or reedy tissue) fibers and ties with them. Salt crystallization is shown by SEM, which means that the ions are uniformly arranged. Based on the study and behavior of laboratory specimens as well as SEM images, it can be claimed that TSFC is made as same as an ancient secret mummy technics.
